TECHNICAL NOTE 1965-39

9 SEPTEMBER 1965

#### ABSTRACT

The Intercom program in the Haystack pointing system provides communications between the pointing system and an experimenter at Haystack using the console keyboard-typewriter. A user at the Millstone or the West Ford site may also direct the pointing system via a teletypewriter. The structure of the program, the calling sequence for it, and the conventions affecting the operator are described.

## I. INTRODUCTION

INTERCOM is an independent closed subroutine used in the Haystack Pointing System to provide communication between the operator of the system and the various programs which point the antenna. The routine also has the facility for allowing the operator of the West Ford antenna system to communicate with Univac 490 programs operating on that device. Programs which use INTERCOM specify the format for input and/or output by format specification tables referred to in the calling sequence. The basic input-output device used by INTERCOM is the console typewriter-printer provided with the Univac 490. However, when operating with the West Ford system, a standard teletypewriter (Model 28) is used instead for input-output.

All messages, both input and output, may be fully logged on the high-speed printer, using the Haystack system subprogram PRLOG, as well as on the console typewriter-printer. Thus, if the operator chooses to terminate printing on the console device, he will still have a complete record of all messages prepared by INTERCOM.

## II. PROGRAM SPECIFICATIONS

### Calling Sequence

From User Program:

RJP        U(INTERCOM)  
U-TAG      XXXXX,YYYYY  
Normal return

XXXXX = location of output specification table; and  
YYYYY = location of input specification table. If  
XXXXX = 0, no output activity will take place; if  
YYYYY = 0, no input will be expected; if both XXXXX  
and YYYYY = 0, control will be returned to the normal  
return after cycling once through the system. When-  
ever control is returned to the normal return, all  
input-output activity is completed.

From Master Control Program (MCP):

RJP        L(INTERCOM)  
Attention return  
Normal return

### Communication with West Ford Teletypewriter

To indicate that the West Ford teletypewriter is to be used as the basic communication device with the Haystack console serving only as monitor, the Univac 490 operator must set Jump Key 3 on the computer control board. When INTERCOM finds this, it sets up for conversion of all information to or from teletype code and operates through an additional input-output channel. The 490 console is disabled for input but prints everything that is printed on the West Ford teletypewriter, both input and output. All special control keys perform the same functions on the West Ford and the Haystack keyboards.

### Control Characters

<u>Haystack</u>	<u>West Ford</u>	<u>Meaning</u>
C/R	C/R (carriage return)	Terminates input, causes INTERCOM to evaluate input string for format validity, limits not exceeded, etc. If input is acceptable, causes * to be printed. If no input expected, terminates output.
?	?	Deletes current input and allows operator to start over. Causes the message NOT ACCEPTED to be printed.
<input type="checkbox"/> (SPEC)	#	Forces limit check, i.e., if limit had been exceeded, this key will cause the input value to be accepted regardless of limit. Causes the message ACCEPTED to be printed.
<input type="checkbox"/> (or †)	(bell)	Attention symbol; causes transfer of control to attention return in MCP.

### Operational Conventions

Any output information may be cut off at any time by hitting either a control character key or a data character key (except when parallel output on the high speed printer is unavailable if it was desired). A carriage return with indentation, or a line feed, depending on the action called for in the input specification table, will be issued followed by that character (or the appropriate message, if one of the control characters was hit). If input is expected, that character will be treated as the first character of the input string. If no input is expected, the character is ignored.

After a limit has been exceeded, a carriage return will cause no operation. The operator must hit either a question

mark to delete the entry or the SPEC key to force the answer in spite of the limit, or he may begin immediately to type the new answer which will automatically delete the previous entry. Once this has been done the carriage return key will again perform its normal function.

Up to 300 characters may be output in any one output message. Since the teleprinter page is only 72 character positions wide, however, the user must make provision for issuing his own carriage return and line feed.

The space character is printed but not recognized for numerical input. It is accepted, though, for alphanumeric character string input.

Carriage positioning conventions are designed so that it is always possible to distinguish information typed by the computer (output) from that typed by the operator (input). Output information always begins at the left margin of the log paper. It may extend over several lines, but each line should begin at the left margin (unless spaces are deliberately programmed into the output message, which is not recommended). Input information will always be started on the next line below the last line of output. The input message would begin either indented five spaces from the left margin or directly below the first space after the output message, depending on an indicator bit in the input specification table.

#### High-Speed Printer Output

If Jump Key 1 is not set on the computer control board, there is activated a series of routines that cause all messages, both input and output, to be printed in their entirety on the high-speed printer. (Note that the normal condition is for printer output; setting Jump Key 1 inhibits printer output.) This provides a complete log of operator activity since, even if the operator terminates an output message before completion on the console printer by commencing the input response, the entire message will be printed on the high-speed (line) printer. Indentation is identical to what would appear on the console printer, but vertical spacing is compressed to single spacing between lines.

An additional option is provided for using the various output formatting and conversion routines in INTERCOM as a means for conveniently printing internally-stored information on the line printer without printing on the console printer. This requires a call to INTERCOM with no input indicated and a special bit setting in the output specification table. This is further described in the section explaining the output specification entry.

### Error Conditions

FORMAT ERROR - This message is typed by INTERCOM after the operator has completed typing the input message and hit carriage return if his input violated one of the requirements of the input specification. For example, if numeric input was specified and the operator typed an alphabetic character, or if an octal number was specified and the operator typed an 8 or 9, etc. After typing the error message, INTERCOM will give a carriage return, enough spaces to line up the new answer with the erroneous one, and re-type as much of the input as correctly met the specifications. The operator may proceed to finish the input message correctly, again terminating with the carriage return. This process will be repeated as long as incorrect input is typed. An incorrect input may not be forced to be accepted but the entire input string may be deleted by typing a question mark.

PROGRAM ERROR - This message is typed by INTERCOM if an output message cannot be properly converted to the format specified by the output specification table, or if either of the specification tables is improperly coded. In short, it implies that the program which called INTERCOM is in error and there is nothing the operator can do to cause or correct this condition. INTERCOM will return control to the normal return of the MCP and the program which caused the error will not be resumed.

MAX LIMIT, MIN LIMIT - These messages are typed by INTERCOM if the upper or lower limit given in the input specification table is exceeded. The message will occur after the operator hits the carriage return terminating the input string. The operator then has the three options described above under Operational Conventions, namely, to start a new input string directly, to force the entry past the limit check, or to delete the previous entry. It is important

to note that once this error message has been typed, the location specified to receive the input entry has had that entry stored in it; therefore it is not possible to delete the entry, then hit carriage return and assume that the receiving location has the same contents as before the call to INTERCOM.

### Specification Tables

Two distinct types of specification tables may be referenced by INTERCOM, each with its own rules for proper preparation. The output specification table consists of one or more separate output specification entries. If there are more than one, the routine will link together the output messages indicated and type each in its own format with a single call to INTERCOM. Inputs may not be linked in this manner; thus the input specification table will always consist of only one entry.

### Output Specification Entry

The first word of the output specification will contain the format description of what is to be printed. The second word will contain, in the lower half, the location of the information to be output. The upper half of the word will contain:

All ones (77777), meaning there is nothing more to be printed.

All zeros (00000), meaning the following location contains the first word of the next output specification entry to be processed.

The location of the next output specification to be processed (must not be location 00000, 00001, 77776, or 77777).

If line printer output only is desired, this half-word in the first output specification entry of the table should contain either a -1 (77776) if there is nothing more to be printed, or a +1 (00001) if the following location contains the first word of another entry.

There is no provision for indicating printer-only operation in an entry which points to the location of the next entry.

The following format descriptions are acceptable for output specification entries:

- F $\beta$  means that a 60-bit floating-point value is to be printed in exponential form with  $\beta$  digits to the right and one digit to the left of the decimal point; for example, a format description of F6 would result in a printout of the form:  
1.234567E-2.
- X $\beta$ By means that a 30-bit value is to be printed out as a fixed-point decimal number whose radix point is to the right of bit  $\gamma$  (the 30 bits being counted 0 to 29 from right to left),  $\beta$  numerals ( $\beta=1$  to 9) expressing the fraction and as many digits as required for the integer portion. ( $\gamma=0$  implies an integer.) The integer portion is followed by a decimal point whether or not a fractional portion follows.
- D means that a 30-bit value is to be printed as a signed decimal integer with leading zeros suppressed.
- O means that a 30-bit value is to be printed out as a 10-digit octal integer.
- A means that the second entry will contain the location of one or more words containing a string of six-bit (Fieldata) alphanumeric characters which will be terminated by a word of all ones.

#### Input Specification Entry

The first word of the input specification table will contain the format description. The second word will contain, in the lower half, the location into which the input information is to be placed (converted into internal computer form). If this information requires more than one

word (double-length floating-point numbers or an alpha string of characters), this location is the first location of the information to be stored.

The upper half of the second word will contain two indicator bits to specify carriage positioning prior to input and whether or not limit checking is desired.

To specify a carriage return, line feed and usual identification, the upper half of the second word is coded as a one (00001). A line-feed-only specification is coded as zero. The input information would then begin immediately following the output, but on the next line.

To specify limit checking the upper half of the second word is coded as 10. No limit checking is coded as 00. Thus, to specify both carriage return and limit check the upper half would be coded as 11. If limit checking is indicated, there will be a third entry containing the lower limit and a fourth entry for the upper limit. If the converted number is double-length, the third and fourth entries will similarly be double-length.

The following format descriptions are acceptable for the input specification table:

F means that the input number is to be converted to a 60-bit internal format floating-point number. The forms of a number which may be input are:

57  
5.7E+1  
5.7E1  
57.0  
57.  
.57E2  
570E-1

X $\gamma$  means that a number is to be converted to a 30-bit fixed-point binary number with the radix point to the right of bit  $\gamma$ . The input format of the number is the same as for floating-point numbers.

D means that a signed decimal integer is to be converted to a 30-bit binary number. (Omission of sign implies positive.)

- 0 means that a signed octal integer is to be converted to a 30-bit binary number. (Omission of sign implies positive.)
- Y means that a YES or NO is to be typed next. If a YES is typed, a one will be placed in the location specified in the second entry; if a NO, a zero will be placed there.
- L $\alpha$  means that from 1 to  $\alpha$  alphabetic letters (A to Z) are to be typed.
- N $\alpha$  means that from 1 to  $\alpha$  numerals are to be typed.
- M $\alpha$  means that from 1 to  $\alpha$  characters of any mixture are to be typed.
- W $\phi$  means that the character to be typed must be  $\phi$  where  $\phi$  is some specific character.

$\alpha$  may not exceed 300, (the size of the character buffer used for both input and output.)

### Examples

To output a string of characters, such as a statement requiring no reply, an entry would be made to INTERCOM from the calling program by:

RJP	U(INTERCOM)
U-TAG	OUTSPEC,0

where OUTSPEC is the location of the output specification table.

The output specification table would be written in SPURT, as follows:

OUTSPEC	FD 0	A
	77777	MESSAGELOC

MESSAGELOC	FD 3	FIRST NUMBER
	77777	77777

To input only a number to be converted to floating-point and to store that number in XX, the calling sequence would be:

	RJP	U(INTERCOM)
	0	INSPEC
INSPEC	FD 0	F
	0	XX

To both output the statement above and input the previously specified number, the following entry could be made:

RJP	U(INTERCOM)
U-TAG	OUTSPEC, INSPEC

The output and input specification tables as written above would be used.

To link together several output messages with different formats and require another format for input, the coding below might be used. (This particular sequence of code would serve as an octal-to-decimal converter which would print the decimal equivalent of the previous input number and then await new input.)

	RJP	U(INTERCOM)	CALL INTERCOM
	U-TAG	SPECTBLOUT,SPECTBLIN	
	JP	\$-2	RETURN TO TYPEOUT LAST
	COMMENT		INPUT AND AWAIT NEXT
SPECTBLOUT	FD 1	A	ALPHA OUTPUT
	00000	DECMESSAGE	POINT TO MESSAGE
	FD 1	D	DECIMAL OUTPUT
	NEXTSPEC	NUMBERLOC	POINT TO NUMBER
NEXTSPEC	FD 1	A	ALPHA OUTPUT
	77777	HOCTMSG	POINT TO MESSAGE
DECMESSAGE	FD 4	DECIMAL EQUIVALENT =	
	77777	77777	TERMINATE ALPHA STRING
HOCTMSG	FD 3	OCTAL NUMBER =	
	77777	77777	TERMINATE ALPHA STRING

NUMBERLOC	00000	00144	
SPECTBLIN	FD 1	0	OCTAL INPUT
	10	NUMBERLOC	LINE FEED AND LIMIT CHECK
	00000	00000	LOWER LIMIT = 0
	00000	01000	UPPER LIMIT = 1000

This coding could produce the following log on the console printer:

```

(a) DECIMAL EQUIVALENT = 100 OCTAL NUMBER =
(b)                                     678 FORMAT ERROR
(c)                                     67*
(d) DECIMAL EQUIVALENT = 55 OCTAL NUMBER =
(e)                                     2233 MAX LIMIT=0000001000
(f)                                     7654 MAX L
(g)                                     ACCEPTED
(h) DECIMAL EQUIVALENT = 4012 OCTAL NUMBER =

```

#### Notes:

- Line (b) - Digit 8 is not an octal digit, hence caused format error.
- Line (e) - Number typed was larger than 1000, hence caused limit check error.
- Line (f) - Number typed was larger than 1000, hence caused limit check error. Operator did not wait for entire error message to print, but hit SPEC key to force typein in spite of exceeding limit.
- Line (g) - Message typed as result of hitting SPEC key.

### III. SUBROUTINE DESCRIPTIONS

#### INTERCOM

##### Function

To print a message on the console printer (and/or the line printer) consisting of alphabetic information, fixed-point, floating-point, octal integer or decimal integer converted from internal computer representation, and to accept similar types of input from the console typewriter or a remote teletypewriter.

##### Calling Sequence

RJP     U(INTERCOM)  
U-TAG   XXXX,YYYY  
Normal return

(XXXXX = location of output specification table)  
(YYYYY = location of input specification table)

##### Input

Output and input specification tables (see Section II).

##### Output

Printed output on console printer, line printer, or remote teleprinter.

Converted values of input information stored in location given by input specification table.

##### Subroutines Used

PUTFORMINT, COMPROC, WESTOUT, WESTIN, HSPOUT.

### Storage Areas Read

None.

### Storage Areas Written

INTOUTSWO, CASESET, INTOUTSW, ACTIVITY  
SPECTBLS, PRINTSW, BUFFCOUNT, BUFFER  
KILLOUTSW, BUFSLOT

### Method

INTERCOM interprets calling sequence and, through use of PUTFORMINT, prepares the output message string. It initiates the output buffer, calls WESTOUT if Jump Key 3 is set indicating that the West Ford console should also receive the output message, and calls HSPOUT if line printer output is also indicated (Jump Key 1 not set). If no output is indicated, INTERCOM sets the output completion bit in the ACTIVITY word and bypasses initiating any output buffer. Once all appropriate outputs are initiated, INTERCOM exits to an address set up by COMPROC, which must be called first for initialization. This address is normally in the MCP of the pointing system and control remains with the MCP until output is complete or terminated by the operator and the input, if indicated, is correctly accepted, converted, limit checked and stored in the user's area as performed by COMPROC. COMPROC then jumps back to the exit portion of INTERCOM, returning to the user program via the normal return. If neither input nor output is indicated, INTERCOM merely cycles once through the MCP and COMPROC, then returns to the user program without any teletypewriter action.

### Error Conditions

For operator error conditions, see Error Conditions in Section II. Program error conditions cause a jump to the routine called ERROR with a 0 in the A register indicating an invalid call to INTERCOM. The message "PROGRAM ERROR XXXXX" is printed where XXXXX is the location of the call to INTERCOM.

## COMPROC

### Function

To initialize the interrupt answering routines, test for output or input completed, interpret, check, convert and store the input and return control to the user program when input is correct.

### Calling Sequence

RJP L(INTERCOM)  
Attention return  
Normal return

### Input

ACTIVITY - a status register set by the interrupt answering routines.

BUFFER - an area containing the string of input characters.

### Output

INTERCOM program messages indicating error conditions or valid input.

### Subroutines Used

INFORMINT, WESTOUT, WESTIN, HSPACC, HSPGIN,  
HSPATTN, HSPNOTACC, SPACERITE, ERROR

### Storage Areas Read

ACTIVITY, SPECTBLS, BUFSLLOT, BUFFCOUNT

### Storage Areas Written

SLOTSTOR, ACTIVITY, LOCININT (42), LOCOUTINT (62),  
LOCTTYIN (40), LOCTTYOUT (60), BUFSLOT  
BUFFER

(Locations 40, 60, 42, and 62 are the hardware interrupt locations for input and output on channels 0 and 2, respectively.)

### Method

COMPROC is called by MCP to respond to an operator's use of the control characters. It examines the ACTIVITY word to decide whether to exit immediately back to the MCP, process completed input data, exit to the attention return, delete input up to this point, etc. When all input is correct, COMPROC will jump back to the exit portion of INTERCOM, returning control to the user program.

### Error Conditions

An error of any type causes a jump to the routine called ERROR with a code in the A register. The codes are interpreted as follows:

- 0 - program error; invalid call to INTERCOM
- 20 - maximum limit exceeded
- 21 - minimum limit exceeded
- other - format error; input cannot be correctly interpreted

## INTOUT

### Function

To answer output interrupts serving two types of output:  
1) the output message strings prepared by INTERCOM or COMPROC;  
and 2) the single characters echoed back to the console printer by INTIN, the input interrupt answering routine. Routine serves both console printer and remote teletypewriter.

### Calling Sequence

From location 62 (the Internal Output Interrupt location for channel 2) or location 60 (the location for channel 0) the instruction

RJP INTOUT

is executed by the hardware when an output buffer on channel 2 or channel 0 is exhausted. The return from INTOUT releases the interlock set by the hardware interrupt and returns control to the user's program at the point at which the interrupt occurred.

### Input

None.

### Output

ACTIVITY - not changed if only single character input is being returned to printer; set to 4 if output message string is complete.

### Subroutines Used

WESTOUT, WESTIN

### Storage Areas Read

SPECTBLS

### Storage Areas Written

ACTIVITY

### Method

A switch setting INTOUTSW0 determines which of the two types of output is being processed. If single character echoing is being performed, the routine immediately sets up another input buffer and exits. If message strings are being processed, the specification table is examined to see if carriage return and indentation is requested or only line feed and the appropriate spacing output characters are given (without further interrupt required). Then the ACTIVITY word is set to 4, an input buffer initiated and the routine releases interlock and exits.

### Error Conditions

None.

## INTIN

### Function

To answer input interrupts for the console typewriter. Can terminate output and examine the input character to see if it is a control character. If a control character, it processes it accordingly setting the appropriate bit in the ACTIVITY word; if not, it stores the input character in the next available slot in the buffer and initiates an output buffer to echo the character back to the printer.

### Calling Sequence

From location 42 (the Internal Input Interrupt location for channel 2) the instruction

RJP INTIN

is executed by the hardware when the single word (character) input buffer connected to channel 2 becomes filled. The return from INTIN releases the interlock set by the hardware interrupt and returns control to the point at which the interrupt occurred.

### Input

BUFIN - the single character buffer

### Output

ACTIVITY - 10 if input complete (carriage return)  
          4 if output terminated  
          2 if deletion (question mark)  
          1 if attention (attention symbol)

### Subroutines Used

WESTOUT, WESTIN, ERROR

### Storage Areas Read

BUFIN, SPECTBLS, BUFSLOT, BUFFER

### Storage Areas Written

ACTIVITY, BUFSLOT

### Method

If output is in progress when INTIN is called, that output is terminated and either a carriage return, line feed and indentation is given or only a line feed depending on the input specification table. Then the input character is examined. If it is one of the control characters, the appropriate bit is set in the ACTIVITY word and the routine exits after re-initiating the input buffer. If not a control character, it is stored in the next slot in the BUFFER, BUFSLOT is incremented, and the character is output back to the console printer and to the remote teletypewriter if West Ford communication is indicated.

### Error Conditions

If BUFSLOT, when incremented, exceeds the limit on the BUFFER size, currently set to  $300_{10}$ , the effect is as if a carriage return had been issued. Presumably, a format error will be detected by COMPROC since no input specification allows for more than 300 characters.

## TTYININT

### Function

To answer input interrupts for the remote teletypewriter (at West Ford). The routine interprets the character, echoes it, sets a case switch if the character is a shift, otherwise translates the character to Fielddata code and passes it on to INTIN for normal input character processing.

### Calling Sequence

From location 40 (the Internal Input Interrupt location for channel 0) the instruction

RJP TTYININT

is executed by the hardware when a single word (character) input buffer connected to channel 0 becomes filled. The return from TTYININT releases the interlock set by the hardware interrupt and returns control to the point at which the interrupt occurred.

### Input

TTYINWD - the single character buffer.

### Output

See output of INTIN.

### Subroutines Used

INTIN

### Storage Areas Read

TTYINWD, TTYTBL

### Storage Areas Written

BUFINWD

### Method

The teletype to Fielddata translation table has letter shift characters in the lower portion of the table and figure shift characters in the higher portion. The base address of the table is set to one or the other of these portions by the corresponding shift character after which the Fielddata character corresponding to any teletype character may be accessed directly. This character is placed in BUFINWD, simulating the hardware function of filling the buffer and allowing INTIN to process the character exactly as though it came from the console typewriter.

### Error Conditions

None.

## WESTOUT

### Function

The West Ford teletypewriter output routine tests Jump Key 3 to see if communication is desired with the West Ford device. If so, it translates the output message string prepared by INTERCOM or COMPROC from Fielddata to teletype code, inserting shift characters as necessary and initiates an output buffer to West Ford, with or without monitor as the instruction preceding the call indicates.

### Calling Sequence

```
IN   KEYIN, W(BUFINWD), MONITOR (Optional)
OUT  KEYOUT, W(ANYTHING), MONITOR (MONITOR optional)
RJP  WESTOUT
Normal return
```

### Input

Output buffer of Fielddata characters indicated by OUT instruction preceding call.

### Output

Printed output on remote teletypewriter.

### Subroutines Used

None.

### Storage Areas Read

TTYTBL.

### Storage Areas Written

FDBUFCNT, TTYBUF.

### Method

The two instructions preceding the call to WESTOUT are interpreted as follows: if the instruction preceding the call is an OUT with MONITOR, the OUT instruction on channel 0 will likewise be with MONITOR, otherwise the OUT will be without MONITOR. The buffer word indicated by that instruction will be used to show the location and size of the Fielddata buffer to be translated. The instruction preceding that (two prior to the RJP) is examined to see if it is an IN; if so, a corresponding IN is initiated on channel 0.

### Error Conditions

None.

## INFORMINT

### Function

To interpret the input specification table, test the completed input message for proper format, convert to internal computer word representation, store in the user's area, and check for the value within the limits given.

### Calling Sequence

RJP    INFORMINT  
0    location of input spec table  
Error return  
Normal return

### Input

BUFFER - the string of characters containing the input message.

The input specification table indicated.

### Output

The converted value of the input message stored in the user's area.

### Subroutines Used

GREEKCONV

The following routines are called corresponding to the format character given in the input specification table:

<u>Format Character</u>	<u>TEST</u>	<u>STORE</u>	<u>LMTCHK</u>
F	FLOATIN	FLTSRT	SLTLMT
X	FIXIN	NUMSTR	FIXLMT
D	DECIN	NUMSTR	DECLMT
0	HOCTIN	NUMSTR	HOCTLMT

<u>Format Character</u>	<u>TEST</u>	<u>STORE</u>	<u>LMTCHK</u>
Y	YESIN	NUMSTR	NOLMT
L	INPUTLA	STRING	NOLMT
N	INPUTNA	STRING	NOLMT
M	INPUTMA	STRING	NOLMT
W	SPECIN	NUMSTR	NOLMT

#### Storage Areas Read

INCODTBL, INTEGER.

#### Storage Areas Written

BUFSLOT.

#### Method

The routine examines the input specification table to see if characters other than the format character are required to specify gamma (the binary point of a fixed-point number), the number of characters to be input, or the specific character to be typed. If so, these numbers are converted with GREEKCONV and passed on (by being left in the A-register) to the appropriate TEST routine. The appropriate STORE routine stores the converted values in the location(s) indicated in the specification table, after which, if limit checking is indicated, they are tested by the corresponding LMTCHK routine to see if they are within the given limits.

#### Error Conditions

1) Errors may be passed on from the TEST routine and the LMTCHK routine. The contents of the A-register are unchanged so that the individual routines determine the type error.

2) An error return from GREEKCONV causes a 0 (program error) to be placed in the A-register before returning to the error return.

3) If a format character other than those allowed is specified, a program error is indicated.

## PUTFORMINT

### Function

To interpret the Output Specification Table, linking individual entries and causing the internal representations to be converted to the appropriate output form and placed in the output buffer, one character per word.

### Calling Sequence

RJP PUTFORMINT  
0 location of output spec table  
Error return  
Normal return

### Input

The output specification table indicated.

### Output

BUFFER - the string of characters comprising the output message.

### Subroutines Used

GREEKCONV, PUTPREP.

### Storage Areas Read

PUTCODTBL, CHARO, INTEGER.

### Storage Areas Written

None (BUFFER through use of PUTPREP).

### Method

A loop is established for processing each specification entry. Within that loop the format character determines whether there are additional characters in the word for specifying beta (the number of fractional digits to print) or gamma (the binary point of a fixed-point number). If so, they are converted from Fieldata to decimal and given to the calling sequence of PUTPREP. The PUTPREP routine actually calls the conversion routines and unpacks the output characters for storing in the buffer. PUTFORMINT then tests for more entries in the specification table and either repeats the loop or exits accordingly.

### Error Conditions

Any error condition, whether generated by subroutines or by PUTFORMINT coding, causes an exit to the error return with a 0 (program error) in the A-register.

## PUTPREP

### Function

To call the appropriate output conversion routine, unpack the resultant characters and store them with sign, decimal point, etc., in the output buffer.

### Calling Sequence

```
RJP    PUTPREP
U-TAG  XXXXX, YYYYY
Error return
Normal return
```

where XXXXX = location of information to be converted and  
YYYYY = code, gamma, beta as follows:

```
000 CCC GGG GGB BBB
      ~~~ ~~~ ~~~
      code gamma beta
```

### Input

Information in calling sequence.

### Output

BUFFER - the string of characters containing the output message.

BUFFCOUNT - a count of the number of characters in BUFFER.

### Subroutines Used

COTFLT, COFFIX, BINDECINT, BINOCFLD, ZROSUPINT, BUFFSTORE.

### Storage Areas Read

SIGN, IOINTEGER, IOFRACTION, BETA, EXPSIGN, IOEXPONENT  
INTEGER.

### Storage Areas Written

CODE, GAMMA, BETA, BUFFER, BUFFCOUNT

### Method

Completely separate paths are followed for each of the five possible output format characters (codes). Straight Fielddata output is converted within PUTPREP; all other conversions are done with subroutines.

### Error Conditions

Any error condition causes an exit to the error return with a code in the A-register as follows:

11 - output message exceeds size of buffer  
25 - Format Character not valid  
other - as returned from conversion routine

## INPUTLA,INPUTNA,INPUTMA

### Function

To test the input string of characters for proper class: alphabetic, numeric or mixed, respectively.

### Calling Sequence

RJP INPUTXA  
Error return  
Normal return

with the maximum number of characters to be tested in the A-register

### Input

None.

### Output

The appropriate return.

### Subroutines Used

INPUTA.

### Storage Areas Read

None.

### Storage Areas Written

None.

### Method

An index register is loaded with the address of a word containing the upper and lower limits of the character codes within the class indicated by the particular routine. This word is given to INPUTA to test the input string in general.

### Error Conditions

If the string contains a character not between 05 and 37 for INPUTLA or between 57 and 71 for INPUTNA, the appropriate error return is given.

## INPUTA

### Function

To test a string of input characters falling within a pair of Fielddata codes given by the calling routines.

### Calling Sequence

```
ENT B6 ADDRESS
RJP     INPUTA
Error return
Normal return
```

ADDRESS XX YY

where XX is the upper limit and YY the lower limit of the class of characters being tested.

### Input

BUFFER+ (BUFSLOT).

The A-register containing the maximum number of characters to be tested.

### Output

A setting of B6, BUFSLOT.

### Subroutines Used

None.

### Storage Areas Read

BUFFER, BUFSLOT

### Storage Areas Written

BUFSLOT.

### Method

The input buffer beginning at BUFFER + (BUFSLOT) is tested character by character for a space which is ignored, a carriage return which is cleared in the buffer and triggers the normal return, or a character within the limits specified. Any character other than these causes an error return.

### Error Conditions

1. A 10 in the A-register indicates too many characters in the string prior to the carriage return. B6 contains a one.
2. If a character is not within the specified class, the error return is given with a zero in B6.

## DECIN, HOCTIN

### Function

To test the input string for proper decimal or octal format and convert to internal code.

### Calling Sequence

RJP DECIN or RJP HOCTIN  
Error return  
Normal return

### Input

None.

### Output

The appropriate return and the converted number in INTEGER.

### Subroutines Used

NUMIN.

### Storage Areas Read

None.

### Storage Areas Written

BINLMT, CONVERT.

### Method

The appropriate BCD limit, 10 for HOCTIN or 12 for DECIN, is placed in BINLMT and the appropriate conversion routine, INTOCTBIN or INTBCDBIN, respectively, placed in CONVERT. Then the common routine NUMIN is called which actually tests the characters and calls the proper conversion routine.

### Error Conditions

1. The error return from DECIN leaves a 07 in the A-register.
2. The error return from HOCTIN leaves a 06 in the A-register.

## NUMIN

### Function

To test and convert a string of input characters in either octal or decimal form.

### Calling Sequence

RJP NUMIN  
Error return  
Normal return

### Input

BINLMT, CONVERT, BUFFER+(BUFSLOT).

### Output

INTEGER.

### Subroutines Used

INTOCTBIN or INTBCDBIN.

### Storage Areas Read

BINLMT, CONVERT, BUFFER, BUFSLOT.

### Storage Areas Written

SIGN, IOINTEGER (2), NUMDIG.

### Method

The string is first examined for a sign character which is used to set the register SIGN to 1 if minus or to 0 if plus. If no sign is found, the register SIGN is set to 0 and the rest of the string examined. Spaces are ignored. Each number is converted from Fielddata to pure BCD, tested against the maximum limit given in BINLMT, and then packed into IOINTEGER, a 2-register common storage area. The appropriate conversion routine converts the number and leaves it properly signed in INTEGER.

### Error Conditions

If any format condition is not met or if the conversion routine indicates an error, the routine exits to the error return.

## SPECIN

### Function

To test the input string for a particular character.

### Calling Sequence

RJP SPECIN  
Error return  
Normal return

with the Fieldata code of the character to be tested for in the A-register.

### Input

BUFFER+(BUFSLOT)

### Output

INTEGER.

### Subroutines Used

None.

### Storage Areas Read

BUFSLOT, BUFFER.

### Storage Areas Written

INTEGER.

### Method

Spaces are not permitted; the character in BUFFER+ (BUFSLOT) must be precisely that given in the A-register and the next character must be a carriage return. The proper character is placed in the common storage register INTEGER.

### Error Conditions

1. If the input buffer size is exceeded, the error return is made with a 01 in the A-register.
2. If the character was not properly entered, the error return is made with a 10 in the A-register.

## YESIN

### Function

To test the input string for a yes or no answer.

### Calling Sequence

RJP YESIN  
Error return  
Normal return

### Input

BUFFER+(BUFSLOT).

### Output

INTEGER (= 1 for yes, 0 for no).

### Subroutines Used

None.

### Storage Areas Read

BUFFER, BUFSLOT.

### Storage Areas Written

INTEGER.

### Method

Spaces are ignored. Only the first character is tested for Y or N, after which anything may be typed.

### Error Conditions

If neither a Y nor an N is typed as the first non-space character, the routine exits to the error return with an 11 in the A-register.

## FLOATIN, FIXIN

### Function

To test the input string for proper exponential format and convert to either floating- or fixed-point internal form.

### Calling Sequence

RJP FLOATIN or RJP FIXIN  
Error return  
Normal return

### Input

None.

### Output

The appropriate return.

### Subroutines Used

EXPREPEN, CINFLT or CINFIX

### Storage Areas Read

None.

### Storage Areas Written

None.

### Method

EXPREPEN is a common routine for testing input format, after which the appropriate conversion routine is called.

### Error Conditions

If either of the subroutines indicates an error, the routine exits to the error return.

## FXPREPREN

### Function

To test the input string for proper exponential format and get the information into common storage areas.

### Calling Sequence

RJP FXPREPREN  
Error return  
Normal return

### Input

BUFFER

### Output

EXPSIGN, SIGN, IOINTEGER(2), IOFRACTION(2), IOFRACTION(2),  
IOEXPONENT.

### Method

Each portion of the input number is examined separately, beginning with the sign (the absence of which indicates a plus), followed by the integer portion terminated by a decimal point, then by the fraction terminated by an E, then by the sign of the exponent, and finally by the magnitude of the exponent, terminated by a carriage return.

### Error Conditions

Tests are made for the digit count of the integer or fraction portion not exceeding 10, for the exponent not exceeding 40, for all characters to be valid digits, etc. Any violation causes an exit to the error return.

## BINDECINT

### Function

To convert the value in INTEGER from binary to decimal in Fielddata output form.

### Calling Sequence

RJP BINDECINT  
Normal return

### Input

INTEGER.

### Output

IOINTEGER(2), SIGN

### Subroutines Used

None.

### Storage Areas Read

INTEGER

### Storage Areas Written

IOINTEGER(2), SIGN

### Method

Repeatedly divide the quantity in INTEGER, having been forced positive, by  $12_8$  and store the remainder in the appropriate digit position of IOINTEGER or IOINTEGER+1.

### Error Conditions

None.

## INTOCTBIN

### Function

To convert the value in IOINTEGER from octal input form to internal binary form.

### Calling Sequence

RJP INTOCTBIN  
Error return  
Normal return

### Input

IOINTEGER(2), SIGN.

### Output

INTEGER.

### Subroutines Used

None.

### Storage Areas Read

IOINTEGER(2), SIGN.

### Storage Areas Written

INTEGER.

### Method

Each character is tested for the presence of an 8 or 9, which results in an error condition. If not, the good characters are packed into a register that is stored in INTEGER.

### Error Conditions

Non-octal digits result in an exit to the error return.

## INTBCDBIN

### Function

To convert a value in IOINTEGER from integer decimal form to internal binary.

### Calling Sequence

RJP INTBCDBIN  
Error return  
Normal return

### Input

IOINTEGER(2), SIGN.

### Output

INTEGER.

### Subroutines Used

None.

### Storage Areas Read

IOINTEGER(2), SIGN.

### Storage Areas Written

INTEGER.

### Method

Multiply successively higher order digits by  $12_8$  and add to the previous partial product.

### Error Conditions

An overflow in the multiplication process indicates that the value in IOINTEGER was too large to convert to single-word binary and causes an exit to the error return.

## FRABCD BIN

### Function

To convert a value in IOFRACTION from fractional decimal form to internal binary.

### Calling Sequence

RJP FRABCD BIN  
Normal return

### Input

IOFRACTION(2) , SIGN.

### Output

FRACTION.

### Subroutines Used

None.

### Storage Areas Read

IOFRACTION(2) , SIGN.

### Storage Areas Written

FRACTION.

### Method

Multiply successively higher order digits by  $(10/12)_8^n$  and add to the previous partial product (where  $n$  is the decimal power of 10 of the digit being multiplied).

### Error Conditions

None.

## BINDECFA

### Function

To convert a value in FRACTION from internal binary form to fractional decimal form suitable for output.

### Calling Sequence

RJP BINDECFA  
Normal return

### Input

FRACTION.

### Output

IOFRACTION(2), SIGN.

### Subroutines Used

None.

### Storage Areas Read

FRACTION.

### Storage Areas Written

IOFRACTION(2), SIGN.

### Method

Multiply the fraction by 10 (B1), each time converting the high-order four bits to output form and accumulating them in IOFRACTION.

### Error Conditions

None.

## SUPZRO

### Function

To suppress leading zeros in the area defined by the calling sequence, converting them to blanks, but leaving one zero if the entire value is zero.

### Calling Sequence

```
RJP      SUPZRO
U-TAG    AREA,XX      (XX = number of words)
Normal return
```

### Input

Area given by calling sequence.

### Output

Same area.

### Subroutines Used

None.

### Storage Areas Read

Area given by calling sequence.

### Storage Areas Written

Same area.

### Method

Test leading digits for zero, clearing each until a non-zero digit is found or the area exhausted. If the latter, force a single zero in the least significant digit position of the area.

### Error Conditions

None.

## COFRND

### Function

To round off the value in IOINTEGER and IOFRACTION to BETA decimal places.

### Calling Sequence

RJP COFRND  
Normal Return

### Input

IOINTEGER(2), IOFRACTION(2), BETA.

### Output

IOINTEGER(2), IOFRACTION(2)

### Subroutines Used

None.

### Storage Areas Read

IOINTEGER(2), IOFRACTION(2), BETA.

### Storage Areas Written

IOINTEGER(2), IOFRACTION(2).

### Method

The BETA+1st digit is tested for five or greater. If not, it is cleared and the fraction replaced as is; if so, the next higher order digits are tested for 9's to see if the carry will propagate upwards. This process continues from IOFRACTION through to IOINTEGER until a digit less than 9 is found at which point 1 is added to it and the value cleared up and prepared for output with BETA digits, zero or greater in IOFRACTION.

### Error Conditions

None.

## COFFIX

### Function

To convert the fixed-point value indicated by the calling sequence to output fixed point format with BETA decimal places printing.

### Calling Sequence

RJP      COFFIX  
U-TAG    ADDRESS,GAMMA  
Normal return

### Input

Value in address given in calling sequence.

### Output

IOINTEGER(2) , IOFRACTION(2) , SIGN.

### Subroutines Used

BINDECINT, BINDECFA, COFRND, SUPZRO.

### Storage Areas Read

Address given in calling sequence.

### Storage Areas Written

SIGN, INTEGER, FRACTION, IOINTEGER(2) , IOFRACTION(2)  
(by subroutines).

### Method

The value is made positive and its true sign temporarily stored. It is then separated into its integer and fractional portions by the binary point (GAMMA) given in the calling sequence. Each is separately converted to output form and the entire value rounded to BETA decimal places with leading zeros suppressed.

### Error Conditions

None

## CINFIX

### Function

To convert the input value in the various storage registers to a single fixed-point binary quantity with the binary point given by the calling sequence.

### Calling Sequence

RJP      CINFIX  
U-TAG    ADDRESS,GAMMA  
Error return  
Normal return

### Input

IOINTEGER(2), IOFRACTION(2), IOEXPONENT, EXPSIGN, SIGN.

### Output

The address given in the calling sequence.

### Subroutines Used

INTBCDBIN, FRABCD BIN.

### Storage Areas Read

IOINTEGER(2), IOFRACTION(2), IOEXPONENT, EXPSIGN, SIGN,  
INTEGER, FRACTION, NOINTS.

### Storage Areas Written

INTEGER, FRACTION (by subroutines); address given in  
calling sequence, FXCODE.

### Method

After masking off the Fielddata code bits from all numbers, the exponent is converted to binary. The values in IOINTEGER and IOFRACTION are shifted right or left (depending on the sign of the exponent), the number of digit positions indicated by the exponent. Then the integer and the fractional portions are separately converted to binary through the use of subroutines and the results shifted together the number of places given by the binary point (GAMMA) in the calling sequence. This quantity, after adjustment for sign, is then stored in the address given in the calling sequence.

### Error Conditions

If overflow occurs indicating that the integer portion is too large to fit into the number of bit positions available, the routine exits to the error return.

## COTFLT

### Function

To convert the value indicated by the calling sequence from internal floating-point form to output exponential form.

### Calling Sequence

RJP     COTFLT  
U-TAG   ADDRESS,0  
Error return  
Normal return

### Input

Floating-point value in ADDRESS (2).

### Output

IOINTEGER+1, IOFRACTION(2), IOEXPONENT, EXPSIGN, SIGN.

### Subroutines Used

FLTPT, BINDECINT, BINDECFA, COFRND, SUPZRO.

### Storage Areas Read

EXPONENT, FPFRACTION.

### Storage Areas Written

INTEGER, FRACTION, EXPONENT, FPFRACTION, IOINTEGER(2),  
IOFRACTION(2), IOEXPONENT, EXPSIGN, SIGN, SINTEMP.

### Method

The value indicated by the calling sequence is stored as a positive quantity in the common area EXPONENT and FPFRACTION along with temporary storage of the true sign. Separate paths are entered depending on the sign of the exponent; but as the functions are similar, only the positive exponent path will be described.

The number is tested against the floating-point representation of  $10^{10}$  and repeatedly divided by it with corresponding adjustment of IOEXPONENT until it is less. Then it is tested against a table of floating-point representations of powers of ten and divided by the highest one which is less than it, thus making the number in terms of units only. Now the value can be shifted an amount equal to the exponent minus the base (40000) to separate the integer and fractional portions which are each converted separately to output format. The resultant input-output values are rounded to BETA decimal places and zero suppressed. The IOEXPONENT is then converted to decimal for output.

### Error Conditions

If the resultant value of IOEXPONENT is greater than 40, the routine exits to the error return.

## CINFLT

### Function

To convert the input value in the various common storage registers to a floating point number stored in EXPONENT and FPFRACTION.

### Calling Sequence

RJP CINFLT  
Error return  
Normal return

### Input

IOINTEGER(2), IOFRACTION(2), IOEXPONENT, EXPSIGN, SIGN.

### Output

EXPONENT, FPFRACTION.

### Subroutines Used

INTBCDBIN, FRABCDDBIN, FLTPT.

### Storage Areas Read

IOINTEGER(2), IOFRACTION(2), IOEXPONENT, EXPSIGN, SIGN,  
INTEGER, FRACTION

### Storage Areas Written

INTEGER, FRACTION (by subroutines), EXPONENT, FPFRACTION.

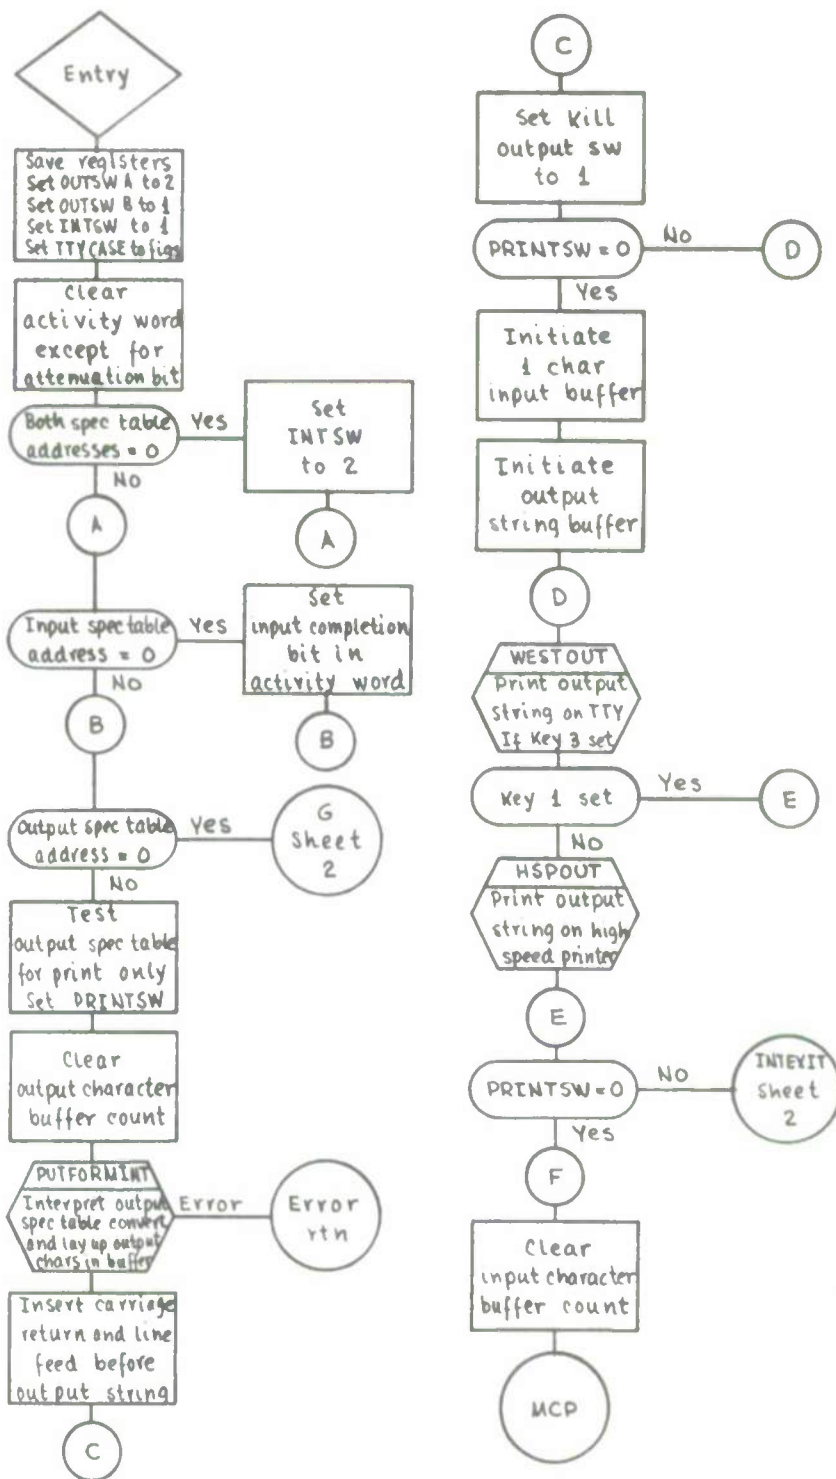

## Method

The input integer and fraction are separately converted to internal binary form after being stripped of Fielddata code bits. The resultant words are normalized by shifting together with a base exponent increased by one for each position shifted out of the integer and into the fraction. Alternatively, if the value were a pure fraction, the exponent would be decreased by one for each bit position the fraction is shifted left until it is normalized. This normalized result is rounded off with appropriate exponent adjustment and stored in a floating-point area.

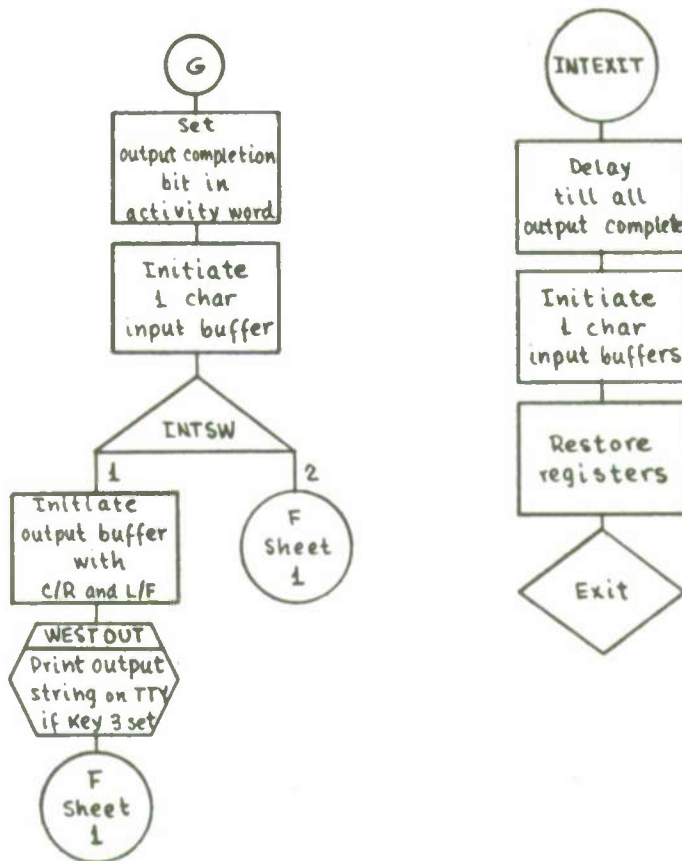

Now the input exponent may be applied through use of the floating-point subroutines. This exponent is separated into the tens and units position for conservation of table storage size. The floating-point value developed thus far is multiplied by the appropriate units digit, also in floating-point form, and that result multiplied by the appropriate multiple of ten. The final result is adjusted for the original sign.

## Error Conditions

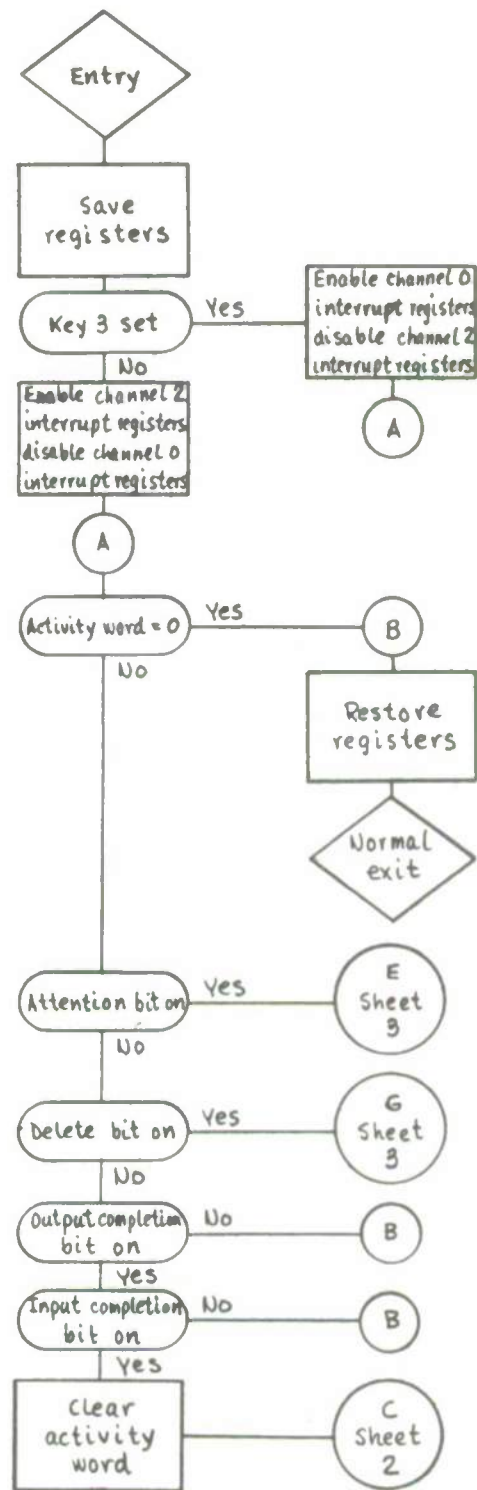

The error return from the INTBCDBIN subroutine causes an exit to the error return.

13. ABSTRACT		
<p>The Intercom program in the Haystack pointing system provides communications between the pointing system and an experimenter at Haystack using the console keyboard-typewriter. A user at the Millstone or the West Ford site may also direct the pointing system via a teletypewriter. The structure of the program, the calling sequence for it, and the conventions affecting the operator are described.</p>
